EXISTENCE, UNIQUENESS AND STABILITY OF PERIODIC SOLUTIONS FOR NONLINEAR NEUTRAL DYNAMIC EQUATIONS

F. BOUCHELAGHEM\(^1\), A. ARDJOUNI\(^2\), AND A. DJOUDI\(^1\)

**Abstract.** The nonlinear neutral dynamic equation with periodic coefficients
\[
[u(t) - g(u(t - \tau(t)))]^\Delta = p(t) - a(t)u^{\sigma}(t) - a(t)g(u^{\sigma}(t - \tau(t))) - h(u(t), u(t - \tau(t)))
\]
is considered in this work. By using Krasnoselskii’s fixed point theorem we obtain the existence of periodic and positive periodic solutions and by contraction mapping principle we obtain the uniqueness. Stability results of this equation are analyzed. The results obtained here extend the work of Mesmouli, Ardjouni and Djoudi [14].

1. **Introduction**

In 1988, Stephan Hilger [10] introduced the theory of time scales (measure chains) as a means of unifying discrete and continuum calculi. Since Hilger’s initial work there has been significant growth in the theory of dynamic equations on time scales, covering a variety of different problems (see [7, 8, 13] and references therein).

Let \(\mathbb{T}\) be a periodic time scale such that \(0 \in \mathbb{T}\). In this article, we are interested in the analysis of qualitative theory of periodic and positive periodic solutions of neutral dynamic equations. Motivated by the papers [1–6, 11, 12, 14, 15, 17] and the references therein, we consider the following nonlinear neutral dynamic equation

\[
[u(t) - g(u(t - \tau(t)))]^\Delta = p(t) - a(t)u^{\sigma}(t) - a(t)g(u^{\sigma}(t - \tau(t))) - h(u(t), u(t - \tau(t))).
\]

Throughout this paper we assume that $a$, $p$ and $\tau$ are real valued rd-continuous functions with $a$ and $\tau$ are positive functions, $id - \tau : T \to T$ is increasing so that the function $u(t - \tau(t))$ is well defined over $T$. The functions $g$ and $h$ are continuous in their respective arguments. To reach our desired end we have to transform (1.1) into an integral equation written as a sum of two mapping, one is a contraction and the other is continuous and compact. After that, we use Krasnoselskii’s fixed point theorem, to show the existence of periodic and positive periodic solutions. We also obtain the existence of a unique periodic solution by employing the contraction mapping principle. In addition to the study of existence and uniqueness, in this research we obtain sufficient conditions for the stability of the periodic solution by using the contraction mapping principle.

The organization of this paper is as follows. In Section 2, we introduce some notations and definitions, and state some preliminary material needed in later sections. We will state some facts about the exponential function on a time scale as well as the fixed point theorems. For details on fixed point theorems we refer the reader to [16]. In Section 3, we establish the existence and uniqueness of periodic solutions. In Section 4, we give sufficient conditions to ensure the existence of positive periodic solutions. The stability of the periodic solution is the topic of Section 5. The results presented in this paper extend the main results in [14].

2. Preliminaries

A time scale is an arbitrary nonempty closed subset of real numbers. The study of dynamic equations on time scales is a fairly new subject, and research in this area is rapidly growing (see [1–6,11,12,15] and papers therein). The theory of dynamic equations unifies the theories of differential equations and difference equations. We suppose that the reader is familiar with the basic concepts concerning the calculus on time scales for dynamic equations. Otherwise one can find in Bohner and Peterson books [7,8,13] most of the material needed to read this paper. We start by giving some definitions necessary for our work. The notion of periodic time scales is introduced in Kaufmann and Raffoul [11]. The following two definitions are borrowed from [11].

Definition 2.1. We say that a time scale $T$ is periodic if there exist a $\omega > 0$ such that if $t \in T$ then $t \pm \omega \in T$. For $T \neq \mathbb{R}$, the smallest positive $\omega$ is called the period of the time scale.

Example 2.1. The following time scales are periodic.

- (a) $T = \bigcup_{i=-\infty}^{\infty}[2(i - 1)h, 2ih], h > 0$, has period $\omega = 2h$.
- (b) $T = h\mathbb{Z}$ has period $\omega = h$.
- (c) $T = \mathbb{R}$.
- (d) $T = \{t = k - q^m : k \in \mathbb{Z}, m \in \mathbb{N}_0\}$, where $0 < q < 1$ has period $\omega = 1$.

Remark 2.1 ([11]). All periodic time scales are unbounded above and below.
Definition 2.2. Let $T \neq \mathbb{R}$ be a periodic time scale with period $\omega$. We say that the function $f : T \to \mathbb{R}$ is periodic with period $T$ if there exists a natural number $n$ such that $T = n\omega$, $f(t \pm T) = f(t)$ for all $t \in T$ and $T$ is the smallest number such that $f(t \pm T) = f(t)$.

If $T = \mathbb{R}$, we say that $f$ is periodic with period $T > 0$ if $T$ is the smallest positive number such that $f(t \pm T) = f(t)$ for all $t \in T$.

Remark 2.2 ([11]). If $T$ is a periodic time scale with period $\omega$, then $\sigma(t \pm n\omega) = \sigma(t) \pm n\omega$. Consequently, the graininess function $\mu$ satisfies $\mu(t \pm n\omega) = \sigma(t \pm n\omega) - (t \pm n\omega) = \sigma(t) - t = \mu(t)$ and so, is a periodic function with period $\omega$.

Definition 2.3 ([7]). A function $f : T \to \mathbb{R}$ is called rd-continuous provided it is continuous at every right-dense point $t \in T$ and its left-sided limits exist, and is finite at every left-dense point $t \in T$. The set of rd-continuous functions $f : T \to \mathbb{R}$ will be denoted by

$$C_{rd} = C_{rd}(T) = C_{rd}(T, \mathbb{R}).$$

Definition 2.4 ([7]). For $f : T \to \mathbb{R}$, we define $f^\Delta(t)$ to be the number (if it exists) with the property that for any given $\varepsilon > 0$, there exists a neighborhood $U$ of $t$ such that

$$\left| (f(\sigma(t)) - f(s)) - f^\Delta(t)(\sigma(t) - s) \right| < \varepsilon |\sigma(t) - s|, \quad \text{for all } s \in U.$$ 

The function $f^\Delta : T^k \to \mathbb{R}$ is called the delta (or Hilger) derivative of $f$ on $T^k$.

Definition 2.5 ([7]). A function $p : T \to \mathbb{R}$ is called regressive provided $1 + \mu(t)p(t) \neq 0$ for all $t \in T$. The set of all regressive and rd-continuous functions $p : T \to \mathbb{R}$ will be denoted by $\mathcal{R} = \mathcal{R}(T, \mathbb{R})$. We define the set $\mathcal{R}^+$ of all positively regressive elements of $\mathcal{R}$ by

$$\mathcal{R}^+ = \mathcal{R}^+(T, \mathbb{R}) = \{ p \in \mathcal{R} : 1 + \mu(t)p(t) > 0, \text{ for all } t \in T \}.$$ 

Definition 2.6 ([7]). Let $p \in \mathcal{R}$, then the generalized exponential function $e_p$ is defined as the unique solution of the initial value problem

$$x^\Delta(t) = p(t)x(t), \quad x(s) = 1, \quad \text{where } s \in T.$$ 

An explicit formula for $e_p(t, s)$ is given by

$$e_p(t, s) = \exp \left( \int_s^t \xi_{\mu(v)}(p(v)) \Delta v \right), \quad \text{for all } s, t \in T,$$

with

$$\xi_h(v) = \begin{cases} \frac{\log(1 + hv)}{h}, & \text{if } h \neq 0, \\ v, & \text{if } h = 0, \end{cases}$$

where log is the principal logarithm function.

Lemma 2.1 ([7]). Let $p, q \in \mathcal{R}$. Then

(i) $e_0(t, s) \equiv 1$ and $e_p(t, t) \equiv 1$;

(ii) $e_p(\sigma(t), s) = (1 + \mu(t)p(t))e_p(t, s)$;
Then there exists a Banach space and let then there is one and only one point. We will need the following lemma whose proof can be found in [11].

\[ \text{Theorem 2.1} \]

\[ \text{Theorem 2.2} \]

\[ \tau \]

\[ e \]

\[ (3.2) \]

\[ a \]

\[ (3.1) \]

\[ \text{Lemma 2.2} ([1]). If } p \in \mathbb{R}^+, \text{ then} \]

\[ 0 < e_p(t, s) \leq \exp \left( \int_s^t p(v) \Delta v \right), \text{ for all } t \in \mathbb{T}. \]

We end this section by stating the fixed point theorems that we employ to help us show the existence, uniqueness and stability of periodic solutions to (1.1) (see [9, 16]).

\[ \text{Theorem 2.1 (Contraction Mapping Principle). Let } (\chi, \rho) \text{ a complete metric space and let } \mathcal{P} : \chi \to \chi. \text{ If there is a constant } \alpha < 1 \text{ such that for any } x, y \in \chi \text{ we have} \]

\[ \rho(\mathcal{P}x, \mathcal{P}y) \leq \alpha \rho(x, y), \]

\[ \text{then there is one and only one point } z \in \chi \text{ with } \mathcal{P}z = z. \]

\[ \text{Theorem 2.2 (Krasnoselskii). Let } M \text{ be a closed bounded convex nonempty subset of a Banach space } (\chi, \|\|). \text{ Suppose that } \mathcal{A} \text{ and } \mathcal{B} \text{ map } M \text{ into } \chi \text{ such that} \]

\[ \begin{align*}
(i) & \quad \mathcal{A} \text{ is compact and continuous;} \\
(ii) & \quad \mathcal{B} \text{ is a contraction mapping;} \\
(iii) & \quad x, y \in M, \text{ implies } \mathcal{A}x + \mathcal{B}y \in M.
\end{align*} \]

\[ \text{Then there exists } z \in M \text{ with } z = \mathcal{A}z + \mathcal{B}z. \]

3. Existence and Uniqueness of Periodic Solutions

Let } T > 0, T \in \mathbb{T} \text{ be fixed and if } \mathbb{T} \neq \mathbb{R}, T = n\omega \text{ for some } n \in \mathbb{N}. \text{ By the notation} \]

\[ [a, b] = \{t \in \mathbb{T}, a \leq t \leq b\}, \]

\[ \text{unless otherwise specified. The intervals } [a, b], (a, b] \text{ and } (a, b) \text{ are defined similarly.} \]

\[ \text{Define } C_T = \{ \varphi \in C(\mathbb{T}, \mathbb{R}) : \varphi(t + T) = \varphi(t) \} \text{ where } C(\mathbb{T}, \mathbb{R}) \text{ is the space of all real-valued rd-continuous functions. Then } (C_T, \|\|) \text{ is a Banach space when it is} \]

\[ \text{endowed with the supremum norm} \]

\[ \|\varphi\| = \max_{t \in [0,T]} |\varphi(t)|. \]

\[ \text{We will need the following lemma whose proof can be found in [11].} \]

\[ \text{Lemma 3.1. Let } x \in C_T. \text{ Then } \|x^\sigma\| = \|x \circ \sigma\| \text{ exists and } \|x^\sigma\| = \|x\|. \]

\[ \text{In this paper we assume that } a \in \mathbb{R}^+, a(t) > 0 \text{ for all } t \in \mathbb{T} \text{ and} \]

\[ (3.1) \quad a(t + T) = a(t), \quad p(t + T) = p(t), \quad (id - \tau)(t + T) = (id - \tau)(t), \]

\[ \text{with } \tau(t) \geq \tau^* > 0 \text{ and} \]

\[ (3.2) \quad \exists e_a(T, 0) > 1. \]
The functions \( g(x), h(x, y) \) are also globally Lipschitz continuous in \( x \) and in \( x \) and \( y \), respectively. That, there are positive constants \( k_1, k_2 \) and \( k_3 \) such that
\[
|g(x) - g(y)| \leq k_1 \|x - y\| \quad \text{and} \quad k_1 < 1
\]
and
\[
|h(x, y) - h(z, w)| \leq k_2 \|x - z\| + k_3 \|y - w\|. \tag{3.4}
\]

**Lemma 3.2.** Suppose (3.1) and (3.2) hold. If \( u \in C_T \), then \( u \) is a solution of (1.1) if and only if
\[
u(t) = g(u(t - \tau(t)))
\]
\[
+ \gamma \left[ \int_t^{t+T} [p(s) - 2a(s)g(u^\sigma(s - \tau(s))) - h(u(s), u(s - \tau(s)))] e_a(t, s) \Delta s, \right.
\]
\[
\left. \right| \Delta s
\]
where
\[
\gamma = (e_a(T, 0) - 1)^{-1}.
\]

**Proof.** Let \( u \in C_T \) be a solution of (1.1). Multiply both sides of (1.1) by \( e_a(t, 0) \) and then integrate from \( t \) to \( t + T \), to obtain
\[
\int_t^{t+T} \left[ (u(s) - g(u(s - \tau(s)))) \Delta e_a(s, 0) \right] \Delta s
\]
\[
= - \int_t^{t+T} a(s) [u^\sigma(s) - g(u^\sigma(s - \tau(s)))] e_a(s, 0) \Delta s
\]
\[
+ \int_t^{t+T} [p(s) - 2a(s)g(u^\sigma(s - \tau(s)) - h(u(s), u(s - \tau(s))))] e_a(s, 0) \Delta s.
\]
Performing an integration by part, we obtain
\[
[u(t) - g(u(t - \tau(t)))] e_a(t, 0) (e_a(T, 0) - 1)
\]
\[
- \int_t^{t+T} a(s) [u^\sigma(s) - g(u^\sigma(s - \tau(s)))] e_a(s, 0) \Delta s
\]
\[
= - \int_t^{t+T} a(s) [u^\sigma(s) - g(u^\sigma(s - \tau(s)))] e_a(s, 0) \Delta s
\]
\[
+ \int_t^{t+T} [p(s) - 2a(s)g(u^\sigma(s - \tau(s)) - h(u(s), u(s - \tau(s))))] e_a(s, 0) \Delta s.
\]
By dividing both sides of the above equation by \( e_a(t, 0) (e_a(T, 0) - 1) \), we arrive at
\[
u(t) = g(u(t - \tau(t))) + (e_a(T, 0) - 1)^{-1}
\]
\[
\times \int_t^{t+T} [p(s) - 2a(s)g(u^\sigma(s - \tau(s))) - h(u(s), u(t - \tau(s)))] e_a(t, s) \Delta s.
\]
The converse implication is easily obtained and the proof is complete. \( \square \)

By applying Theorems 2.1 and 2.2, we obtain in this Section the existence and the uniqueness of periodic solution of (1.1). So, let a Banach space \( (C_T, \|\cdot\|) \), a closed bounded convex subset of \( C_T \),
\[
\mathcal{M} = \{ \varphi \in C_T : \|\varphi\| \leq L \}, \tag{3.6}
\]
with $L > 0$, and by the Lemma 3.2, we define the mapping $\mathcal{P}$ given by

$$(\mathcal{P}\varphi) (t) = g(\varphi(t - \tau(t))) + \gamma \int_{t}^{t+T} [p(s) - 2a(s)g(\varphi^\sigma(s - \tau(s))) - h(\varphi(s), \varphi(s - \tau(s)))] e_{\Theta a}(t, s) \Delta s.$$  

(3.7)

Therefore, we express (3.7) as

$$\mathcal{P}\varphi = A\varphi + B\varphi,$$

where $A$ and $B$ are given by

$$(A\varphi) (t) = \gamma \int_{t}^{t+T} [p(s) - 2a(s)g(\varphi^\sigma(s - \tau(s))) - h(\varphi(s), \varphi(s - \tau(s)))] e_{\Theta a}(t, s) \Delta s$$

and

$$(B\varphi) (t) = g(\varphi(t - \tau(t))).$$

(3.8)

(3.9)

Since $\varphi \in C_T$ and (3.1) holds, we have for any $\varphi \in \mathcal{M}$

$$(A\varphi)(t + T) = \gamma \int_{t+T}^{t+T+T} [p(s + T) - 2a(s + T)g(\varphi^\sigma(s + T - \tau(s + T))) - h(\varphi(s + T), \varphi(s + T - \tau(s + T)))] e_{\Theta a}(t + T, s + T) \Delta s$$

$$= (A\varphi)(t),$$

and

$$(B\varphi)(t + T) = g(\varphi(t + T - \tau(t + T))) = g(\varphi(t - \tau(t))) = (B\varphi)(t).$$

(3.10)

Then

$$\mathcal{A} \mathcal{M}, \mathcal{B} \mathcal{M} \subset C_T.$$

**Theorem 3.1.** Assume that (3.1)–(3.4) hold. Let a constant $L > 0$ defined in $\mathcal{M}$ such that

$$(k_1 L + |g(0)| + \gamma \beta T(\mu + 2\lambda k_1 L + |g(0)| + k_2 L + k_3 L + |h(0, 0)|) \leq L,$$

(3.11)

where

$$\beta = e_a(T, 0), \quad \lambda = \sup_{t \in [0, T]} \{a(t)\}, \quad \mu = \sup_{t \in [0, T]} |p(t)|.$$

Then (1.1) has a $T$-periodic solution.
Proof. First, let \( A \) defined by (3.8), we show that \( A \) is continuous in the supremum norm and the image of \( A \) is contained in a compact set. Let \( \varphi_n \in M \) where \( n \) is a positive integer such that \( \varphi_n \to \varphi \) as \( n \to \infty \). Then

\[
|\langle A\varphi_n \rangle(t) - \langle A\varphi \rangle(t)|
\]

\[
\leq 2\gamma \int_{t}^{t+T} a(s) |g(\varphi_n^{\sigma}(s - \tau(s))) - g(\varphi^{\sigma}(s - \tau(s)))| e_{\ominus a}(t, s)\Delta s
\]

\[
+ \gamma \int_{t}^{t+T} |h(\varphi_n(s), \varphi_n(s - \tau(s))) - h(\varphi(s), \varphi(s - \tau(s)))| e_{\ominus a}(t, s)\Delta s.
\]

Since \( g \) and \( h \) are continuous, the dominated convergence theorem implies,

\[
\lim_{n \to \infty} |\langle A\varphi_n \rangle(t) - \langle A\varphi \rangle(t)| = 0,
\]

then \( A \) is continuous. Now, by (3.3) and (3.4), we obtain

\[
|g(y)| \leq k_1 |y| + |g(0)|,
\]

\[
|h(x, y)| \leq k_2 |x| + k_3 |y| + |h(0, 0)|.
\]

Then, let \( \varphi_n \in M \) where \( n \) is a positive integer, we have

\[
|\langle A\varphi_n \rangle(t)|
\]

\[
\leq \gamma \int_{t}^{t+T} [p(s) + 2a(s) |g(\varphi_n^{\sigma}(s - \tau(s)))| + |h(\varphi_n(s), \varphi_n(s - \tau(s)))|] e_{\ominus a}(t, s)\Delta s
\]

\[
\leq \gamma \int_{t}^{t+T} \left[p(s) + 2a(s) (k_1 \|\varphi_n^{\sigma}\| + |g(0)|) + k_2 \|\varphi_n\| + k_3 \|\varphi_n\| + |h(0, 0)|\right] e_{\ominus a}(t, s)\Delta s
\]

\[
\leq \gamma \beta T (\mu + 2\lambda (k_1 L + |g(0)|) + k_2 L + k_3 L + |h(0, 0)|) \leq L,
\]

by (3.11). Next, we calculate \( (A\varphi_n)^{\Delta}(t) \) and show that it is uniformly bounded. By making use of (3.1) we obtain by taking the derivative in (3.8) that

\[
(A\varphi_n)^{\Delta}(t) = -a(t) (A\varphi_n)^{\sigma}(t) + p(t) - 2a(t) g(\varphi_n^{\sigma}(t - \tau(t))) - h(\varphi_n(t), \varphi_n(t - \tau(t))).
\]

Then, by (3.4) and (3.11) we have

\[
|\langle A\varphi_n \rangle^{\Delta}(t)| \leq \lambda L + \mu + 2\lambda (k_1 L + |g(0)|) + k_2 L + k_3 L + |h(0, 0)| = Q.
\]

Thus the sequence \( (A\varphi_n) \) is uniformly bounded and equicontinuous. Hence, by Ascoli–Arzelà’s theorem \( \mathcal{A}M \) is compact.

Second, let \( B \) be defined by (3.9). Then for \( \varphi_1, \varphi_2 \in M \) we have by (3.3)

\[
|\langle B\varphi_1 \rangle(t) - \langle B\varphi_2 \rangle(t)| = |g(\varphi_1(t - \tau(t))) - g(\varphi_2(t - \tau(t)))|
\]

\[
\leq k_1 \|\varphi_1 - \varphi_2\|.
\]

Hence, \( B \) is contraction because \( k_1 < 1 \).
Finally, we show that if \( \varphi, \phi \in \mathcal{M} \), then \( \| A \varphi + B \phi \| \leq L \). Let \( \varphi, \phi \in \mathcal{M} \) with \( \| \varphi \|, \| \phi \| \leq L \), then
\[
\| A \varphi + B \phi \| \leq k_1 \| \phi \| + |g(0)|
\]
\[
+ \gamma \int_{t}^{t+T} [p(s) + 2a(s) (k_1 \| \varphi \| + |g(0)|)] \, e_{\mathcal{E}_a}(t, s) \Delta s
\]
\[
\leq k_1 L + |g(0)| + \gamma \beta T (\mu + 2\lambda (k_1 L + |g(0)|)) + k_2 L + k_3 L + |h(0, 0)| \leq L,
\]
by (3.11). Clearly, all the hypotheses of the Krasnoselskii’s theorem are satisfied. Thus there exists a fixed point \( z \in \mathcal{M} \) such that \( z = A z + B z \). By Lemma 3.2 this fixed point is a solution of (1.1). Hence, (1.1) has a unique \( T \)-periodic solution.

**Theorem 3.2.** Suppose (3.1)–(3.4) hold. If
\[
(3.12) \quad k_1 + \gamma \beta T (2\lambda k_1 + k_2 + k_3) < 1,
\]
then (1.1) has a unique \( T \)-periodic solution.

**Proof.** Let the mapping \( \mathcal{P} \) be given by (3.7). For any \( \varphi_1, \varphi_2 \in C_T \), we have
\[
\| (\mathcal{P} \varphi_1)(t) - (\mathcal{P} \varphi_2)(t) \|
\]
\[
\leq |g(\varphi_1(t - \tau(t))) - g(\varphi_2(t - \tau(t)))|
\]
\[
+ 2\gamma \int_{t}^{t+T} a(s) |g(\varphi_1^\sigma(s - \tau(s))) - g(\varphi_2^\sigma(s - \tau(s)))| \, e_{\mathcal{E}_a}(t, s) \Delta s
\]
\[
+ \gamma \int_{t}^{t+T} |h(\varphi_1(s), \varphi_1(s - \tau(s))) - h(\varphi_2(s), \varphi_2(s - \tau(s)))| \, e_{\mathcal{E}_a}(t, s) \Delta s
\]
\[
\leq k_1 \| \varphi_1 - \varphi_2 \| + \gamma \int_{t}^{t+T} (2\lambda k_1 + k_2 + k_3) \| \varphi_1 - \varphi_2 \| \, e_{\mathcal{E}_a}(t, s) \Delta s
\]
\[
\leq [k_1 + \gamma \beta T (2\lambda k_1 + k_2 + k_3)] \| \varphi_1 - \varphi_2 \|.
\]
Since (3.12) hold, the contraction mapping principle completes the proof. \( \Box \)

**Corollary 3.1.** Suppose (3.1)–(3.4) hold and let \( \beta, \lambda, \) and \( \mu \) be constants defined in Theorem 3.1. Let \( \mathcal{M} \) defined by (3.6). Suppose there are positive constants \( k_1^*, k_2^* \) and \( k_3^* \) such that for any \( x, y, z, w \in \mathcal{M} \), we have
\[
(3.13) \quad |g(x) - g(y)| \leq k_1^* \| x - y \| \quad \text{and} \quad k_1^* < 1,
\]
\[
(3.14) \quad |h(x, y) - h(z, w)| \leq k_2^* \| x - z \| + k_3^* \| y - w \|
\]
and
\[
(3.15) \quad k_1^* L + |g(0)| + \gamma \beta T (\mu + 2\lambda (k_1^* L + |g(0)|)) + k_2^* L + k_3^* L + |h(0, 0)| \leq L.
\]
Then (1.1) has a \( T \)-periodic solution in \( \mathcal{M} \). Moreover, if
\[
(3.16) \quad k_1^* + \gamma \beta T (2\lambda k_1^* + k_2^* + k_3^*) < 1,
\]
then (1.1) has a unique \( T \)-periodic solution in \( \mathcal{M} \).
Proof. Let the mapping \( \mathcal{P} \) defined by (3.7). Then the proof follow immediately from Theorem 3.1 and Theorem 3.2.

Notice that the constants \( k_1^*, k_2^* \) and \( k_3^* \) may depend on \( L \).

4. Existence of Positive Periodic Solutions

It is for sure that existence of positive solutions is important for many applied problems. In this Section, by applying the Krasnoselskii’s fixed point theorem and some techniques, to establish a set of sufficient conditions which guarantee the existence of positive periodic solutions of (1.1). So, we let \( (\chi, \| \cdot \|) = (C_T, \| \cdot \|) \) and \( \mathcal{M}(E, K) = \{ \varphi \in C_T : E \leq \varphi(t) \leq K \text{ for all } t \in [0, T] \} \), for any \( 0 < E < K \). We assume that, there exist constants \( a_1, a_2, g_1 \) and \( g_2 \) such that for all \( (t, x, y, z) \in [0, T] \times [E, K]^3 \) we have

\[
\begin{align*}
(4.1) & \quad 0 \leq g_1, \quad 0 \leq g_2 < 1, \quad -g_1 y \leq g(y) \leq g_2 y, \\
(4.2) & \quad 0 < a_1 \leq a(t) \leq a_2, \\
(4.3) & \quad (E + g_1 K) a_2 \leq p(t) - 2a_1(t) g(z) - h(x, y) \leq (1 - g_2) Ka_1. 
\end{align*}
\]

Theorem 4.1. Assume that (3.1)–(3.4) and (4.1)–(4.3) hold. Then (1.1) has at least one positive \( T \)-periodic solution in \( \mathcal{M}(E, K) \).

Proof. By Lemma 3.2, it is obvious that (1.1) has a solution \( \varphi \) if and only if \( \mathcal{P} \varphi = \varphi \) has a solution \( \varphi \). Let \( \mathcal{A}, \mathcal{B} \) defined by (3.8), (3.9) respectively. A change of variable \( t \mapsto t + T \) in (3.8) and (3.9) show that for any \( \varphi \in \mathcal{M}(E, K) \) and \( t \in \mathbb{R} \)

\[
(4.4) \quad \mathcal{A}(\mathcal{M}(E, K)) \subseteq C_T, \quad \mathcal{B}(\mathcal{M}(E, K)) \subseteq C_T.
\]

Arguing as in the Theorem 3.1, the operator \( \mathcal{A} \) is compact. Next, we claim that \( \mathcal{A} \) is continuous. It is sufficient to show that \( \mathcal{A}(\mathcal{M}(E, K)) \) is uniformly bounded and equicontinuous in \([0, T]\). Notice that (4.2) and (4.3) ensure that

\[
\| \mathcal{A} \varphi \| \leq \sup_{t \in [0, T]} \left| \gamma \int_{t}^{t+T} \left[ p(s) - 2a(s) g(\varphi^\sigma(s - \tau(s))) - h(\varphi(s), \varphi(s - \tau(s))) \right] e_{\ominus a}(t, s) \Delta s \right| \\
\leq (1 - g_2) K \gamma a_1 \sup_{t \in [0, T]} \int_{t}^{t+T} e_{\ominus a}(t, s) \Delta s \\
\leq (1 - g_2) K, \quad \text{for all } \varphi \in [E, K]
\]

and

\[
\left| (\mathcal{A} \varphi)^\mathcal{A}(t) \right| \leq a(t) \left| (\mathcal{A} \varphi)^\sigma(t) \right| + \left| p(t) - 2a_1(t) g(\varphi^\sigma(t - \tau(t))) - h(\varphi(t), \varphi(t - \tau(t))) \right| \\
\leq a_2 (1 - g_1) K + (1 - g_1) a_1 K \\
= (a_2 + a_1) (1 - g_1) K, \quad \text{for all } (t, \varphi) \in [0, T] \times [E, K],
\]
which give that $A(M(E, K))$ is uniformly bounded and equicontinuous in $[0, T]$. Hence by Ascoli–Arzela’s theorem $A$ is compact. Next, let $B$ defined by (3.9), for all $\varphi_1, \varphi_2 \in M(E, K)$ and $t \in \mathbb{R}$, we obtain by (3.3)

$$
\|B\varphi_1 - B\varphi_2\| \leq k_1 \|\varphi_1 - \varphi_2\|.
$$

Thus $B$ is a contraction. Moreover, by (4.1)–(4.3), we infer that for all $\varphi, \phi \in M(E, K)$ and $t \in \mathbb{R}$

$$(A\varphi)(t) + (B\phi)(t) = g(\phi(t - \tau(t)))
+ \gamma \int_t^{t+T} [p(s) - 2a(s)g(\varphi^\sigma(s - \tau(s))) - h(\varphi(s), \varphi(s - \tau(s)))] e_{\mathbb{E}}(t, s)\Delta s
\leq g_2K + (1 - g_2) K\gamma \int_t^{t+T} a(s) e_{\mathbb{E}}(t, s)\Delta s = K.
$$

On the other hand,

$$(A\varphi)(t) + (B\phi)(t) = g(\phi(t - \tau(t)))
+ \gamma \int_t^{t+T} [p(s) - 2a(s)g(\varphi^\sigma(s - \tau(s))) - h(\varphi(s), \varphi(s - \tau(s)))] e_{\mathbb{E}}(t, s)\Delta s
\geq -g_1K + (E + g_1K) \gamma \int_t^{t+T} a(s) e_{\mathbb{E}}(t, s)\Delta s = E,
$$

which imply that

$$
(A\varphi + B\phi) \in M(E, K), \quad \text{for all } \varphi, \phi \in M(E, K) \text{ and } t \in \mathbb{R}.
$$

Clearly, all the hypotheses of the Krasnoselskii’s theorem are satisfied. Thus there exists a fixed point $z \in M(E, K)$ such that $z = Az + Bz$. By Lemma 3.2 this fixed point is a solution of (1.1). Hence, (1.1) has a positive $T$-periodic solution. This completes the proof. \qed

**Theorem 4.2.** Assume that (3.1)–(3.4) hold. Suppose that there exist constants $E$, $K$, $a_1$, $a_2$, $g_1$, $g_2$ and $t_0 \in [0, T]$ satisfying (4.1)–(4.3) with

$$
0 \leq E < K,
$$

and either

$$
(E + g_1K) a_2 < p(t_0) - 2a(t_0)g(z) - h(x, y), \quad \text{for all } x, y, z \in [E, K],
$$

or

$$
a(t_0) < a_2.
$$

Then (1.1) has at least one positive $T$-periodic solution in $M(E, K)$, with $E < u \leq K$ for each $t \in [0, T]$. 

Proof. As in the proof of Theorem 4.1, we conclude similarly that (1.1) has an $T$-periodic solution $u \in M(E, K)$. Now we assert that $u(t) > E$ for all $t \in [0, T]$. Otherwise, there exists $t^* \in [0, T]$ satisfying $u(t^*) = E$. In view of (3.5), (3.7), (4.1) and (4.6), we have

$$E = g(u(t^* - \tau(t^*)))$$

$$+ \gamma \int_{t^*}^{t^* + T} [p(s) - 2a(s)g(u^\sigma(s - \tau(s))) - h(u(s), u(s - \tau(s)))] e_{\exists a}(t^*, s) \Delta s$$

$$\geq \gamma \int_{t^*}^{t^* + T} [p(s) - 2a(s)g(u^\sigma(s - \tau(s))) - h(u(s), u(s - \tau(s)))] e_{\exists a}(t^*, s) \Delta s$$

$$- g_1 K,$$

which implies that

$$0 \geq \gamma \int_{t^*}^{t^* + T} [p(s) - 2a(s)g(u^\sigma(s - \tau(s))) - h(u(s), u(s - \tau(s)))] e_{\exists a}(t^*, s) \Delta s$$

$$- (E + g_1 K)$$

$$= \gamma \int_{t^*}^{t^* + T} [p(s) - 2a(s)g(u^\sigma(s - \tau(s))) - h(u(s), u(s - \tau(s)))]$$

$$- (E + g_1 K)a(s) \Delta s$$

$$\geq \gamma \int_{t^*}^{t^* + T} e_{\exists a}(t^*, s) \Delta s$$

$$\geq 0,$$

which contradicts (4.9).

Assume that (4.7) holds. By means of (4.2), (4.3), (4.7) and the continuity of $h, g, a, p, \tau$ and $u$, we get that

$$\gamma \int_{t^*}^{t^* + T} e_{\exists a}(t^*, s) \Delta s$$

$$\geq \gamma \int_{t^*}^{t^* + T} e_{\exists a}(t^*, s) \Delta s$$

$$\geq 0,$$

which contradicts (4.9). This completes the proof. \qed
Example 4.1. Consider (1.1), where
\[ T = \mathbb{R}, \quad p(t) = 3 + \frac{\sin t}{5}, \quad a(t) = 1 + \frac{\cos t}{4}, \quad \tau(t) = 2\cos^2 t, \]
\[ g(x) = -\frac{x \sin x}{20}, \quad \text{for all } x \in \mathbb{R}, \]
\[ h(x, y) = 1 + \sin^2 x + \cos^2 y, \quad \text{for all } (x, y) \in \mathbb{R}^2. \]
Let \( T = 2\pi, \quad K = 10, \quad E = 1, \quad g_1 = g_2 = \frac{1}{20}, \quad a_1 = \frac{3}{4}, \quad a_2 = \frac{5}{4}, \quad k_1 = \frac{11}{20}. \) It is easy to see that (3.3), (3.4) hold. Notice that
\[ (E + g_1 K) a_2 = \frac{15}{8} < \frac{195}{40} = 3 - \frac{1}{5} + 2 \left(1 - \frac{1}{4}\right) \frac{1}{20} + 2 \]
\[ \leq p(t) - 2a(t) g(z) - h(x, y) \leq 3 + \frac{1}{5} + 2 \cdot \frac{5}{4} \cdot \frac{1}{20} + 3 = \frac{253}{40} \]
\[ < \frac{285}{40} = (1 - g_2) K a_1, \quad \text{for all } (t, x, y, z) \in \mathbb{R}^4. \]
That is, (4.3) is satisfied. Thus Theorem 4.1 yields that (1.1) has a positive \( 2\pi \)-periodic solution in \( M(1, 10). \)

5. Stability of Periodic Solutions

This Section concerned with the stability of a \( T \)-periodic solution \( u^* \) of (1.1). Let \( v = u - u^* \) then (1.1) is transformed as
\[ (v(t) - G(v(t - \tau(t))))^2 \]
\[ = -a(t) v^2(t) - a(t) G(v^2(t - \tau(t))) - H(v(t), v(t - \tau(t))), \]
where
\[ G(v(t - \tau(t))) = g(u^*(t - \tau(t)) + v(t - \tau(t))) - g(u^*(t - \tau(t))) \]
and
\[ H(v(t), v(t - \tau(t))) = h(u^*(t) + v(t)), u^*(t - \tau(t)) + v(t - \tau(t)) - h(u^*(t), u^*(t - \tau(t))). \]
Clearly, (5.1) has trivial solution \( v \equiv 0 \), and the conditions (3.3) and (3.4) hold for \( G \) and \( H \) respectively. To arrive at the Lemma 3.2, as in the proof of this Lemma, multiply both sides of (5.1) by \( e_{a}(t, 0) \) and then integrate from 0 to \( t \), to obtain
\[ v(t) = (v(0) - G(v(-\tau(0)))) e_{\ominus a}(t, 0) + G(v(t - \tau(t))) \]

\[ - \int_{0}^{t} \left[ 2a(s) G(v^2(s - \tau(s))) + H(v(s), v(s - \tau(s))) \right] e_{\ominus a}(t, s) ds. \]
Thus, we see that \( v \) is a solution of (5.1) if and only if it satisfies (5.2). Assumed initial function
\[ v(t) = \psi(t), \quad t \in [m_0, 0], \]
with $\psi \in C([m_0, 0], R)$, $[m_0, 0] = \{ s \leq 0 \mid s = t - \tau(t), \ t \geq 0 \}$. For the stability definition we refer the reader to the book [9].

Define the set $S_\psi$ by

$$S_\psi = \{ \varphi \in C_T, \| \varphi \| \leq R, \varphi(t) = \psi(t) \text{ if } t \in [m_0, 0], \varphi(t) \to 0 \text{ as } t \to \infty \},$$

for some positive constant $R$. Then, $(S_\psi, \| \cdot \|)$ is a complete metric space where $\| \cdot \|$ is the supremum norm.

**Theorem 5.1.** If (3.1), (3.3), (3.4) and

$$e_{\Theta_a}(t, 0) \to 0 \text{ as } t \to \infty,$$

$$t - \tau(t) \to \infty \text{ as } t \to \infty,$$

$$k_1 + \int_0^t (2\lambda k_1 + k_2 + k_3) e_{\Theta_a}(t, s)\Delta s \leq \alpha < 1,$$

hold. Then every solution $v(t, 0, \psi)$ of (5.1) with small continuous initial function $\psi$, is bounded and asymptotically stable.

**Proof.** Let the mapping $\mathcal{F}$ defined by $\psi(t)$ if $t \in [m_0, 0]$ and

$$(\mathcal{F}\varphi)(t) = (\psi(0) - G(\psi(-\tau(0)))) e_{\Theta_a}(t, 0) + G(\varphi(t - \tau(t)))$$

$$- \int_0^t [2a(s)G(\varphi(\tau(\tau(s)))) + H(\varphi(s), \varphi(s - \tau(s)))] e_{\Theta_a}(t, s)\Delta s,$$

if $t \geq 0$. Since $G$ and $H$ are continuous, it is easy to show that $\mathcal{F}\varphi$ is continuous. Let $\psi$ be a small given continuous initial function with $\| \psi \| < \delta$ ($\delta > 0$). Then using the condition (5.6) and the definition of $\mathcal{F}$ in (5.7), we have for $\varphi \in S_\psi$

$$| (\mathcal{F}\varphi)(t) | \leq | \psi(0) - G(\psi(-\tau(0))) | e_{\Theta_a}(t, 0) + k_1 R$$

$$+ R \int_0^t (2\lambda k_1 + k_2 + k_3) e_{\Theta_a}(t, s)\Delta s$$

$$\leq (1 + k_1)\delta + k_1 R + R \int_0^t (2\lambda k_1 + k_2 + k_3) e_{\Theta_a}(t, s)\Delta s$$

$$\leq (1 + k_1)\delta + \alpha R \leq R,$$

which implies $\| \mathcal{F}\varphi \| \leq R$, for the right $\delta$. Next we show that $(\mathcal{F}\varphi)(t) \to 0$ as $t \to \infty$. The first term on the right side of (5.7) tends to zero, by condition (5.4). Also, the second term on the right side tends to zero, because of (5.5) and the fact that $\varphi \in S_\psi$. Let $\epsilon > 0$ be given, then there exists a $t_1 > 0$ such that for $t > t_1, \varphi(t - \tau(t)) < \epsilon$. By the condition (5.4), there exists a $t_2 > t_1$ such that for $t > t_2$ implies that

$$e_{\Theta_a}(t, t_2) < \frac{\epsilon}{\alpha R}.$$
Thus for \( t > t_2 \), we have
\[
\left| \int_0^t [2a(s)G(\varphi^\sigma(s - \tau(s))) + H(\varphi(s), \varphi(s - \tau(s)))] e_{\alpha}(t, s) \Delta s \right|
\leq R \int_0^{t_1} (2\lambda k_1 + k_2 + k_3) e_{\alpha}(t, s) \Delta s + \epsilon \int_0^t (2\lambda k_1 + k_2 + k_3) e_{\alpha}(t, s) \Delta s
\leq R e_{\alpha}(t, t_2) \int_0^t (2\lambda k_1 + k_2 + k_3) e_{\alpha}(t_2, s) \Delta s + \alpha \epsilon
\leq \alpha R e_{\alpha}(t, t_2) \alpha + \alpha \epsilon < \alpha \epsilon + \epsilon.
\]
Hence, \((\mathcal{F}\varphi)(t) \to 0\) as \( t \to \infty \). It is natural now to prove that \( \mathcal{F} \) is contraction under the supremum norm. Let \( \varphi_1, \varphi_2 \in S_\varphi \). Then
\[
|((\mathcal{F}\varphi_1)(t)) - ((\mathcal{F}\varphi_2)(t))| \\
\leq |G(\varphi_1(t - \tau(t))) - G(\varphi_2(t - \tau(t)))| \\
+ 2\lambda \int_0^t |G(\varphi_1^\sigma(s - \tau(s))) - G(\varphi_2^\sigma(s - \tau(s)))| e_{\alpha}(t, s) \Delta s \\
+ \int_0^t |H(\varphi_1(s), \varphi_1(s - \tau(s))) - H(\varphi_2(s), \varphi_2(s - \tau(s)))| e_{\alpha}(t, s) \Delta s
\leq k_1 \|\varphi_1 - \varphi_2\| + \int_0^t (2\lambda k_1 + k_2 + k_3) \|\varphi_1 - \varphi_2\| e_{\alpha}(t_2, s) \Delta s
\leq \left[ k_1 + \int_0^t (2\lambda k_1 + k_2 + k_3) e_{\alpha}(t_2, s) \Delta s \right] \|\varphi_1 - \varphi_2\|
\leq \alpha \|\varphi_1 - \varphi_2\|.
\]
Hence, the contraction mapping principle implies, \( \mathcal{F} \) has a unique fixed point in \( S_\varphi \), which solves (5.1), bounded and asymptotically stable.

**Theorem 5.2.** If (3.1), (3.3), (3.4) and (5.6) hold. Then, the zero solution is stable.

**Proof.** The stability of the zero solution of (5.1) follows simply by replacing \( R \) by \( \epsilon \) in the above theorem. \( \square \)
